**KEYWORDS** Kidney transplantation, acute rejection; donor profile

**ABSTRACT** A retrospective study was carried out at INHS Asvini to analyse certain aspects of kidney transplantation and compare the data generated with available data from developed countries in literature. The etiology of end stage renal disease, age and sex distribution of recipients, donor profile, HLA typing results, episodes of acute rejection, causes of post transplant morbidity and mortality were studied and compared with some of the other contemporary studies. Males outnumbered females, as recipients while the number of female donors was more. All 6 alleles were identified in only sixty- four samples by microlymphocytotoxicity-based methods while by DNA based HLA typing all six alleles were identified in nearly 80% patients with class II in over 90 % cases. In this study perioperative causes and infections led to loss of graft in five patients each.
